EXECUTIVE SUMMARY

The CTA's bus system is at 67% of its pre-COVID ridership as of 2024, and that number has barely moved in two years. The system-wide figure looks like progress. Route-level data is less encouraging. This analysis scored 128 bus routes and 143 rail stations using six years of daily ridership data from the Chicago Data Portal and found that 43 bus routes and 48 rail stations qualify as High Risk, carrying a fraction of their pre-COVID ridership with no trend toward recovery. Two Red Line stations, Berwyn and Lawrence, recorded exactly zero boardings across all of 2022–2024 after

averaging nearly 3,000 daily riders each before COVID. Both stations were closed in 2021 for the Red-Purple Modernization project and did not reopen until July 2025, so what looks like a demand collapse is really a construction closure. The first step is figuring out why the remaining routes haven't recovered: auditing service levels on High Risk corridors, cross-referencing with equity data to find the communities most exposed, and treating the gap as a policy problem that requires a specific answer.

1. BACKGROUND AND CONTEXT

Between 2018 and 2019, the CTA averaged 652,921 bus riders per day. By 2022 that had fallen to 437,428, a loss of roughly 215,000 daily riders. Two years later, the system is still at 67% of its pre-COVID baseline.

Figure 1: CTA Bus System Daily Ridership (2018–2024). Orange = pre-COVID, blue = post-COVID recovery.

The headline recovery figure hides more than it reveals. System-wide averages are dominated by the highest-volume routes, and those routes have recovered reasonably well. The problem sits elsewhere, in lower-volume routes serving specific neighborhoods, where ridership has stalled or continued falling long after the acute crisis ended.

Routes running at a fraction of their former ridership still cost money to operate. The CTA received billions in federal pandemic relief through the CARES Act and the American Rescue Plan, which kept service levels intact through the worst of the crisis. Those funds are finite and largely spent. The agency is now facing a structural budget gap with fewer riders, less fare revenue, and no emergency lifeline to fall back on. The pressure to cut underperforming routes isn't hypothetical. It's the next conversation. For residents in neighborhoods where the bus is the primary way to reach work, a clinic, or a grocery store, the difference between a route that gets cut and one that gets restructured is not abstract.

This analysis asked a simple question before that conversation happens: which CTA routes are underperforming, and how badly?

2. DATA AND METHODOLOGY

The analysis draws on three datasets published by the Chicago Transit Authority through the Chicago Data Portal:

- CTA Daily Boarding Totals: system-wide ridership by date
- Bus Ridership by Route: daily boardings by route and day type (weekday, Saturday, Sunday/holiday)
- Rail Ridership by Station: daily boardings by station

Two time windows define the comparison: 2018–2019 as the pre-COVID baseline, and 2022–2024 as the recovery period. The years 2020 and 2021 were excluded from both

windows. They represent the acute crisis period, when ridership collapsed system-wide and many routes were running on emergency schedules. Including those years would muddy both the baseline and the recovery picture. The goal is to compare normal operations before COVID against what the system looks like now, not to measure the depth of the trough.

Each bus route and rail station was scored on a 0–100 composite scale based on four factors:

- Post-COVID ridership volume (average daily boardings, 2022–2024)
- Recovery rate (what percentage of pre-COVID ridership has returned)
- Trend direction (whether ridership is still growing or has stalled through 2024)
- Day type consistency (whether the route serves riders on weekdays and weekends, or only in narrow windows)

One design choice worth flagging: the score measures proportional underperformance, not absolute ridership volume. A high-ridership route that has recovered only 50% of its former riders scores similarly to a low-ridership route in the same position. This is intentional. A large route that has lost half its riders is a real failure of service delivery, regardless of how many riders it still has. Focusing only on low-volume routes would miss those cases entirely.

Routes were ranked by score and divided into three tiers: **High Risk** , **Moderate** , and **Stable** . The tiers are relative to the rest of the CTA system, not to any external benchmark. A Stable route has recovered well compared to its peers; that doesn't necessarily mean it's back to full health.

There's also a real gap in what these datasets can tell us: they don't include service-level data: route frequency, hours of operation, or schedule changes. A route running every 30 minutes can't realistically attract the ridership of one running every 10 minutes, and this analysis can't separate demand-side decline from supply-side cuts. Where findings suggest a route has collapsed, that warrants direct investigation rather than a simple conclusion about demand.

3. FINDINGS

3a. The system-wide recovery gap

Of the 128 bus routes with complete data in this analysis, roughly one-third sit in each tier:

Tier	Bus routes	Rail stations
High Risk	43	48
Moderate	42	47
Stable	43	48
Total	128	143

The Stable tier is reassuring but geographically concentrated. High-ridership routes along major corridors (Western, Pulaski, Cottage Grove) have recovered to roughly 70–80% of pre-COVID levels and are trending upward. They carry a disproportionate share of total system ridership, which is why the top-line number looks better than the route-level picture.

The High Risk tier is the concern. 43 bus routes and 48 rail stations are carrying significantly less ridership than before COVID with no clear sign of improvement. That is one in three routes in this dataset.

Bus Route Recovery vs. Ridership Lost (Post-COVID)

Figure 2: Each dot is one route. Position = drop magnitude vs. recovery rate. Color = tier (green = Stable, orange = Moderate, red = High Risk). Size = pre-COVID ridership volume.

3b. Underutilized routes by tier

High Risk bus routes

The worst-scoring routes aren't low-volume routes that were always marginal. Several carried well over 1,000 daily riders before COVID.

Route 121 averaged 1,104 daily boardings in 2018–2019. In 2022–2024, that number is 300, a 73% decline with a recovery rate of 27.1%. Route 120 is nearly identical: from 801 daily riders to 215, recovering at 26.9%. Route 135 went from 3,186 daily riders to 1,289, recovering at 40.5%.

These aren't routes where demand evaporated because neighborhoods changed. The drop is too sharp and too consistent. Something happened to ridership on these routes during COVID and it hasn't come back.

One route worth calling out specifically is Route 52. With roughly 5,000 daily riders in the post-COVID period, it doesn't look like a struggling route at first glance. But before COVID it was carrying closer to 10,000. That's a 49.3% recovery rate, less than half its former ridership. Because the scoring model measures proportional loss rather than raw volume, Route 52 ranks as High Risk. A route that once served 10,000 people and now serves 5,000 isn't fine. It has a hole in it.

Figure 3: Top 20 bus routes ranked by composite underutilization score (0–100). Darker red = higher risk.

Figure 4: Blue = post-COVID average daily riders. Gray = pre-COVID baseline. The gap between them is what was lost.

High Risk rail stations

Rail tells a more extreme version of the same story, though this one has a known cause. Berwyn station on the Red Line averaged 2,845 daily boardings in 2018–2019. In the 2022–2024 period, it recorded exactly zero, every single day of the three-year window. Lawrence station, also on the Red Line, averaged 2,762 daily boardings before COVID and recorded the identical pattern: zero boardings on all 1,096 days.

A flat zero across three full years isn't ridership decline, it's a closed station. Both stops closed in 2021 as part of the CTA's Red-Purple Modernization (RPM) project, a full rebuild of four North Side Red Line stations, and did not reopen until July 20, 2025. The scoring model still flags them as High Risk because the underlying ridership numbers say so, and that's the correct behavior: the model isn't supposed to know why a station went dark, only that it did. But the right response isn't an investigation into the cause. The cause is public record. The right response is tracking whether ridership actually returns now that the stations are open again.

Moderate-tier routes

The middle tier is less dramatic but harder to read. Recovery rates range from roughly 40% to 65% of pre-COVID levels. Some routes here are trending upward. Others have been flat since 2022. Without service-level data, it's hard to say whether these routes are on a path back toward their old ridership or whether 50–60% is the new normal.

Figure 5: Stacked bars show how ridership breaks down by day type. Routes like 156 show stronger weekend demand relative to weekday, which points to restructuring rather than cuts.

Route 156 is the clearest restructuring candidate in the dataset. Weekday ridership has barely recovered, but Saturday and Sunday boardings are holding relatively steady. The riders are still there; they're just not commuting. Running a standard weekday-heavy schedule for a route that has shifted toward weekend use is a mismatch between service design and actual demand. Cutting this route would be solving the wrong problem; a redesigned schedule is the more obvious fix.

Route 52 tells a different story. Unlike Route 156, ridership on Route 52 has collapsed across every day type: weekdays, Saturdays, and Sundays alike. There's no scheduling explanation for that. The riders haven't shifted to weekends; they've left. Combined with its proportional ranking as High Risk, Route 52 is one of the routes that most warrants direct investigation before any investment decision is made.

Stable routes

The best-performing routes are concentrated in the highest-density corridors and aren't a cause for concern. What they are is a useful reference point: the CTA's strongest routes sit at 70–80% of pre-COVID levels. Its weakest are at 25–40%. Two years into the recovery period, that gap hasn't moved.

4. RECOMMENDATIONS

RECOMMENDATION 1

Audit service levels on all 43 High Risk bus routes before cutting any of them

This analysis identifies 43 High Risk bus routes based on ridership outcomes, but it can't determine whether low boardings reflect low demand or inadequate service. A route running every 30 minutes with unreliable on-time performance won't attract riders, and the data here looks identical to a route where neighborhood demand has genuinely declined. Cutting a route that's underperforming because of poor service quality makes the problem worse and damages trust with the riders who still depend on it.

CTA operations should conduct service-level audits for all 43 High Risk routes in the next budget cycle, documenting current frequency, span of service, and on-time performance. Outreach to residents in affected neighborhoods should be part of that process; riders know things that schedules don't capture. The audit is what distinguishes a route that needs investment from one that needs restructuring.

Knowing which situation applies to each route is the precondition for any spending decision.

RECOMMENDATION 2

Prioritize recovery investment on High Risk routes serving transit-dependent neighborhoods

A route that dropped from 3,000 daily riders to 800 in a neighborhood with low car ownership is a different problem than the same drop in a corridor where most residents drive. The underutilization score treats both the same.

The 43 High Risk bus routes should be cross-referenced against census data on vehicle ownership, median income, and commute mode. Routes serving high transit-dependency areas with low recovery should be first in line for targeted investment: increased frequency, extended service hours, or schedule restructuring. If the routes that haven't recovered are concentrated in specific communities, which an equity overlay would show quickly, that's not a data pattern. That's a decision someone made, or failed to make, about who gets reliable transit service.

RECOMMENDATION 3

Track post-reopening recovery at Berwyn and Lawrence as a reactivation project, not a demand problem

Berwyn and Lawrence stations recorded zero boardings on every single day of the 2022–2024 window after carrying roughly 5,600 combined daily riders before COVID. That pattern rules out organic demand shift. Both stations were closed in 2021 for the CTA's Red-Purple Modernization project and reopened July 20, 2025, so the zero-ridership period in this dataset is fully explained by construction, not by riders choosing to leave.

These two stations still deserve attention, just not the kind the raw ridership numbers imply. Former riders spent roughly four years without service at these stops and don't automatically know the stations are open again. Reaching them requires direct outreach in Edgewater and Uptown (transit ads, community

organizations, signage at nearby stops that were serving as substitutes), not just a schedule update on the CTA website.

Set a measurable recovery target, something like 60% of pre-2020 boardings within 18 months of the July 2025 reopening, and track monthly boarding data at both stations against that baseline. If ridership stalls well below that mark a year or more after reopening, that points to a real service or awareness problem worth its own investigation. Right now, the honest read of the data is that these two stations are mid-recovery from a known, finite disruption, and the right move is to measure that recovery, not re-litigate its cause.

5. CONCLUSION

Chicago's transit system has recovered from COVID, partially. The system-wide numbers suggest steady progress. Route-level data tells a different story: one in three bus routes and one in three rail stations in this analysis are classified High Risk, carrying a fraction of their pre-COVID ridership with no clear trend toward improvement.

Automatic cuts would be the wrong response, and so would treating every underperforming route the same way. A route struggling because of poor service quality is a different problem than one in a neighborhood where travel patterns have genuinely shifted. Berwyn and Lawrence are something else entirely: a station closure that the data flags correctly, with a cause on public record and a reopening already underway. What matters now is whether ridership actually comes back now that service has resumed, not relitigating why it dropped in the first place.

The CTA has the ridership data to see where the gaps are. What's been missing is a framework for acting on them at the route level rather than the system level. This analysis tries to build one.

Data: Chicago Data Portal. Analysis period: 2018–2019 (pre-COVID baseline) and 2022–2024 (recovery period). Composite scoring model weights ridership volume, COVID recovery rate, trend direction, and day type consistency on a 0–100 scale. Full methodology available upon request.
